Abstract

This paper studies first order methods for solving smooth minimax optimization problems \( \min_x \max_y g(x, y) \) where \( g(\cdot, \cdot) \) is smooth and \( g(x, \cdot) \) is concave for each \( x \). In terms of \( g(\cdot, y) \), we consider two settings — strongly convex and nonconvex — and improve upon the best known rates in both. For strongly-convex \( g(\cdot, y) \), \( \forall y \), we propose a new direct optimal algorithm combining Mirror-Prox and Nesterov’s AGD, and show that it can find global optimum in \( \tilde{O}(1/k^2) \) iterations, improving over current state-of-the-art rate of \( O(1/k) \). We use this result along with an inexact proximal point method to provide \( \tilde{O}(1/k^{1/3}) \) rate for finding stationary points in the nonconvex setting where \( g(\cdot, y) \) can be nonconvex. This improves over current best-known rate of \( O(1/k^{1/5}) \). Finally, we instantiate our result for finite nonconvex minimax problems, i.e., \( \min_x \max_{1 \leq i \leq m} f_i(x) \), with nonconvex \( f_i(\cdot) \), to obtain convergence rate of \( O(m^{1/3}\sqrt{\log m}/k^{1/3}) \).

1 Introduction

In this paper we study smooth minimax problems of the form:
\[
\min_{x \in \mathcal{X}} \max_{y \in \mathcal{Y}} g(x, y), \quad g : \mathcal{X} \times \mathcal{Y} \to \mathbb{R}, \quad g \text{ is smooth i.e., gradient Lipschitz.} \tag{1}
\]

The problem has applications in several domains such as machine learning [15, 29], optimization [5], statistics [3], mathematics [23], and game theory [31]. Given the importance of these problems, there is an extensive body of work that studies various algorithms and their convergence properties. The vast majority of existing results for this problem focus on the convex-concave setting, where \( g(\cdot, y) \) is convex for every \( y \) and \( g(x, \cdot) \) is concave for every \( x \). The best known convergence rate in this setting is \( O(1/k) \) for the primal-dual gap, achieved for example by Mirror-Prox [34]. This rate is also known to be optimal for the class of smooth convex-concave problems [41]. A natural question is whether we can achieve a faster convergence if we have strong convexity (as opposed to just convexity) of \( g(\cdot, y) \). We answer this in the affirmative, by introducing an algorithm that achieves a convergence rate of \( \tilde{O}(1/k^2) \) for the general smooth, strongly-convex–concave minimax problem. The algorithm we propose is a novel combination of Mirror-Prox and Nesterov’s accelerated gradient descent. This matches the known lower bound of \( \Omega(1/k^2) \) from [41], closing the gap up to a poly-logarithmic factor. There also exists a conceptually simple smoothing technique based indirect algorithm, which prefixes the tolerance of \( \varepsilon \). However, our goal is to find a direct algorithm which does not prefix the tolerance. Other known methods that obtain a rate of \( O(1/k^2) \) in this context are for very special cases, where \( x \) and \( y \) are connected through a bi-linear term or \( g(x, \cdot) \) is linear in \( y \) [45, 20, 14, 8, 49, 16, 48].

1. Optimal

While most theoretical results focus on the convex-concave setting, several real world problems when $A$ we might hope to find an approximate stationary point \([37]\). (i.e., has Lipschitz gradients) and $g(x, \cdot)$ is concave $\forall x \in X$. Convexity, strong convexity and nonconvexity in the first column refers to $g(\cdot, y)$ for fixed $y$. Smoothing schemes are indirect methods using the smoothing technique \([36]\).

Table 1: Comparison of our results with previous state-of-the-art. We assume that $g(\cdot, \cdot)$ is smooth (i.e., has Lipschitz gradients) and $g(x, \cdot)$ is concave $\forall x \in X$. Convexity, strong convexity and nonconvexity in the first column refers to $g(\cdot, y)$ for fixed $y$. Smoothing schemes are indirect methods using the smoothing technique \([36]\).

While most theoretical results focus on the convex-concave setting, several real world problems fall outside this class. A slightly larger class, which captures several more applications, is the class of smooth nonconvex–concave minimax problems, where $g(x, \cdot)$ is concave for every $x$ but $g(\cdot, y)$ can be nonconvex. For example, finite minimax problems, i.e., $\min_x \max_{y \leq 1} f_i(x) = \min_x \max_{y \leq 1} \sum_{i=1}^m y_i \cdot f_i(x) := g(x, y)$ belong to this class, and so do smooth nonconvex constrained optimization problems \([25]\). In addition, several machine learning problems with non-decomposable loss functions \([22]\) also belong to this class.

In this general nonconvex concave setting however, we cannot hope to find global optimum efficiently as even the special case of nonconvex optimization is NP-hard. Similar to nonconvex optimization, we might hope to find an approximate stationary point \([57]\).

Our second contribution is a new algorithm and a faster rate for the general smooth nonconvex–concave minimax problem. Our algorithm is an inexact proximal point method for the nonconvex function $f(x) := \max_{y \leq 1} g(x, y)$. The key insight is that the proximal point method in each iteration results in a strongly-convex concave minimax problem, for which we use our improved algorithm to obtain the overall computation/iteration complexity of $\tilde{O}(1/k^{1/3})$ thus improving over the previous best known rate of $O(1/k^{1/5})$ \([18]\). More recently, independent to our work, a smoothing based algorithm has also been proposed to achieve the same $O(k^{-1/3})$ rate \([26]\).

Finally, we specialize our result to finite minimax problems, i.e., $\min_x \max_{1 \leq i \leq m} f_i(x)$ where $f_i(x)$ can be nonconvex function but each $f_i$ is a smooth function; nonconvex constrained optimization problems can be reduced to such finite minimax problems. For these, we obtain a rate of $\tilde{O}(m^{1/2} \sqrt{\log m}/k^{1/3})$ total gradient computations which improves upon the state-of-the-art rate $O(m^{1/4}/k^{1/4})$ \([11]\) in this setting as well.

**Summary of contributions:** See also Table 1

1. Optimal $O(1/k^2)$ convergence rate for smooth, strongly-convex – concave problems, improving upon the previous best known rate of $O(1/k)$ for a direct algorithm and,
2. $\tilde{O}(1/k^{1/3})$ convergence rate for smooth, nonconvex – concave problems, improving upon the previous best known rate of $O(1/k^{1/5})$.

**Related works:** For strongly-convex-concave minimax problems with special structures, several algorithms have been proposed. In an increasing order of generality, \([14, 49, 50]\) study optimizing a strongly convex function with linear constraints, which can be posed as a special case of minimax optimization, \([35, 8]\) study a minimax problem where $x$ and $y$ are connected only through a bi-linear term $y^T A x$, and \([16, 20]\) study a case where $g(x, \cdot)$ is linear in $y$. In all these cases, it is shown that $O(1/k^2)$ convergence rate is achievable if $g(\cdot, y)$ is strongly-convex $\forall y$. Recently, \([12]\) showed linear convergence of gradient descent ascent for strongly-convex–concave problem with bilinear coupling when $A$ has full row rank. However, it has remained an open question if the fast rate of $O(1/k^2)$ can be achieved for general strongly-convex-concave minimax problems. See \([32, 9, 7, 17, 51, 1]\)

\footnote{While \([18]\) gives a rate of $O(1/k^{1/4})$ with an approximate maximization oracle for $\max_{y \leq 1} g(x, y)$, taking into account the cost of implementing such a maximization oracle gives a rate of $O(1/k^{1/3})$.}
for detailed surveys on the results for the convex-concave minimax problems. For examples and
application of saddle point problems refer \cite{46,19,20,7,43}.

For nonconvex-concave minimax problems, \cite{42} considers both deterministic and stochastic settings,
and proposes inexact proximal point methods for solving smooth nonconvex–concave problems.
In the deterministic setting, their result guarantees an error of $O(1/k^{1/6})$. We note that there
have also been other notions of stationarity proposed in literature for nonconvex-concave minimax
problems \cite{28,40}. These notions however are weaker than the one considered in this paper, in the
sense that, our notion of stationarity implies these other notions (without loss in parameters). For one
such weaker notion, \cite{40} proposes an algorithm with a convergence rate of $O\left(k^{-1/3.5}\right)$. Since
the notion they consider is weaker, it does not imply the same convergence rate in our setting.

We would also like to highlight the works \cite{6,13,33,46,34,47,10} designing efficient algorithms for
solving monotone variational inequalities which generalizes the convex-concave minimax problems.

Notations: $\mathbb{R}$ is the real line and for any natural number $p$, $\mathbb{R}^p$ is the real vector space of dimension $p$.
$\|\cdot\|$ is a norm on some metric space which would be evident from the context. For a convex set $\mathcal{X} \subseteq \mathbb{R}^p$ and
$x \in \mathbb{R}^p$, $\mathcal{P}_\mathcal{X}(x) = \arg\min_{x' \in \mathcal{X}} \|x - x'\|$ is the projection of $x$ on to $\mathcal{X}$. For a differentiable
function $g(x,y)$, $\nabla_x g(x,y)$ is its gradient with respect to $x$ at $(x,y)$. We use the standard big-O
notations. For functions $T, S : \mathbb{R} \rightarrow \mathbb{R}$ such that $0 < \liminf_{x \rightarrow \infty} T(x) < \liminf_{x \rightarrow \infty} S(x)$,
(a) $T(x) = O(S(x))$ means $\limsup_{x \rightarrow \infty} T(x)/S(x) < \infty$; (b) $T(x) = \Theta(S(x))$ means $T(x) = \Theta(S(x))$ and $S(x) = \Theta(T(x))$; and (c) $T(x) = \tilde{O}(S(x))$ means $T(x) = \tilde{O}(S(x)R(x))$ for
some poly-logarithmic function $R : \mathbb{R} \rightarrow \mathbb{R}$.

Paper organization: In Section\cite{2} we present preliminaries and all relevant background. In Section\cite{3} we present our results for strongly-convex–concave setting and in section\cite{4} results for nonconvex–
concave setting. In Section\cite{5} we present empirical evaluation of our algorithm for nonconvex-concave
setting and compare it to a state-of-the-art algorithm. We conclude in Section\cite{6} Several technical
details are presented in the appendix.

2 Preliminaries and background material

In this section, we will present some preliminaries, describing the setup and reviewing some back-
ground material that will be useful in the sequel.

2.1 Minimax problems

We are interested in the minimax problems of the form \cite{1} where $g(x,y)$ is a smooth function.

Definition 1. A function $g(x,y)$ is said to be $L$-smooth if:

$$\max \{\|\nabla_x g(x,y) - \nabla_x g(x',y')\|, \|\nabla_y g(x,y) - \nabla_y g(x',y')\|\} \leq L (\|x - x'\| + \|y - y'\|).$$

Throughout, we assume that $g(x,\cdot)$ is concave for every $x \in \mathcal{X}$. For $g(\cdot, y)$ behavior in terms of $x$,
there are broadly two settings:

2.1.1 Convex-concave setting

In this setting, $g(\cdot, y)$ is convex $\forall \ y \in \mathcal{Y}$. Given any $g$ and $\forall(\tilde{x}, \tilde{y})$, the following holds trivially:

$$\min_{x \in \mathcal{X}} g(x, \tilde{y}) \leq g(\tilde{x}, \tilde{y}) \leq \max_{y \in \mathcal{Y}} g(\tilde{x}, y),$$

which then implies that $\max_{y \in \mathcal{Y}} \min_{x \in \mathcal{X}} g(x, y) \leq \min_{x \in \mathcal{X}} \max_{y \in \mathcal{Y}} g(x, y)$. The celebrated minimax theorem for the convex-concave setting \cite{44} says that if $\mathcal{Y}$ is a compact set then the above
inequality is in fact an equality, i.e., $\max_{y \in \mathcal{Y}} \min_{x \in \mathcal{X}} g(x, y) = \min_{x \in \mathcal{X}} \max_{y \in \mathcal{Y}} g(x, y)$. Furthermore,
young point $(x^*, y^*)$ is an optimal solution to \cite{1} if and only if:

$$\min_{x \in \mathcal{X}} g(x, y^*) = g(x^*, y^*) = \max_{y \in \mathcal{Y}} g(x^*, y). \quad (2)$$

Hence, our goal is to find $\varepsilon$-primal-dual pair $(\tilde{x}, \tilde{y})$ with small primal-dual gap: $\max_{y \in \mathcal{Y}} g(\tilde{x}, y) - \min_{x \in \mathcal{X}} g(x, \tilde{y}) \leq \varepsilon$.

Definition 2. For a convex-concave function $g : \mathcal{X} \times \mathcal{Y} \rightarrow \mathbb{R}$, $(\tilde{x}, \tilde{y})$ is an $\varepsilon$-primal-dual pair of $g$ if
the primal-dual gap is less than $\varepsilon$: $\max_{y \in \mathcal{Y}} g(\tilde{x}, y) - \min_{x \in \mathcal{X}} g(x, \tilde{y}) \leq \varepsilon$.  

3
2.1.2 Nonconvex-concave setting

In this setting the function \( g(\cdot, y) \) need not be convex. One cannot hope to solve such problems in general, since the special case of nonconvex optimization is already NP-hard \( [39] \). Furthermore, the minmax theorem no longer holds, i.e., \( \max_{y \in Y} \min_{x \in X} g(x, y) \) can be strictly smaller than \( \min_{x \in X} \max_{y \in Y} g(x, y) \), and therefore the order of \( \min \) and \( \max \) might be important for a given application i.e., we might be interested only in minimax but not maximin (or vice versa). So, the primal-dual gap may not be a meaningful quantity to measure convergence. In this paper we will focus on the minimax problem: \( \min_{x \in X} \max_{y \in Y} g(x, y) \). One approach, inspired by nonconvex optimization, to measure convergence is to consider the function \( f(x) = \max_{y \in Y} g(x, y) \) and consider the convergence rate to approximate first order stationary points (i.e., \( \nabla f(x) \) is small)\( [42, 18] \).

But as \( f(x) \) could be non-smooth, \( \nabla f(x) \) might not even be defined. It turns out that whenever \( g(x, y) \) is smooth, \( f(x) \) is weakly convex (Definition 4) for which first order stationarity notions are well-studied and are discussed below.

**Approximate first-order stationary point for weakly convex functions:** We first need to generalize the notion of gradient for a non-smooth function.

**Definition 3.** The Fréchet sub-differential of a function \( f(\cdot) \) at \( x \) is defined as the set, \( \partial f(x) = \{ u | \lim_{x' \to x} f(x') - f(x) - \langle u, x' - x \rangle / \|x' - x\| \geq 0 \} \).

In order to define approximate stationary points, we also need the notion of weakly convex function and Moreau envelope.

**Definition 4.** A function \( f : \mathcal{X} \to \mathbb{R} \cup \{ \infty \} \) is \( L \)-weakly convex if,

\[
f(x) + \langle u_x, x' - x \rangle - \frac{L}{2} \|x' - x\|^2 \leq f(x') \quad \text{for all Fréchet subgradients } u_x \in \partial f(x), \text{ for all } x, x' \in \mathcal{X}.
\]

**Definition 5.** For a proper lower semi-continuous (l.s.c.) function \( f : \mathcal{X} \to \mathbb{R} \cup \{ \infty \} \) and \( \lambda > 0 \) \( (\mathcal{X} \subseteq \mathbb{R}^d) \), the Moreau envelope function is given by

\[
f_\lambda(x) = \min_{x \in \mathcal{X}} f(x') + \frac{1}{2\lambda} \|x - x'\|^2.
\]

Lemma 4 (in Appendix B.2) provides some useful properties of the Moreau envelope for weakly convex functions. Now, first order stationary point of a non-smooth nonconvex function is well-defined, i.e., \( x^* \) is a first order stationary point (FOSP) of a function \( f(x) \) if, \( 0 \in \partial f(x^*) \) (see Definition 3). However, unlike smooth functions, it is nontrivial to define an approximate FOSP. For example, if we define an \( \epsilon \)-FOSP as the point \( x \) with \( \min_{u \in \partial f(x)} \|u\| \leq \epsilon \), there may never exist such a point for sufficiently small \( \epsilon \), unless \( x \) is exactly a FOSP. In contrast, by using above properties of the Moreau envelope of a weakly convex function, it’s approximate FOSP can be defined as \( [11] \):

**Definition 6.** Given an \( L \)-weakly convex function \( f \), we say that \( x^* \) is an \( \epsilon \)-first order stationary point (\( \epsilon \)-FOSP) if, \( \|\nabla f_\lambda(x^*)\| \leq \epsilon \), where \( f_\lambda \) is the Moreau envelope with parameter \( 1/2L \).

Using Lemma 4 we can show that for any \( \epsilon \)-FOSP \( x^* \), there exists \( \hat{x} \) such that \( \|\hat{x} - x^*\| \leq \epsilon/2L \) and \( \min_{u \in \partial f(\hat{x})} \|u\| \leq \epsilon \). In other words, an \( \epsilon \)-FOSP is \( O(\epsilon) \) close to a point \( \hat{x} \) which has a subgradient smaller than \( \epsilon \). We note that other notions of FOSP have also been proposed recently such as in \( [40] \). However, it can be shown that an \( \epsilon \)-FOSP according to the above definition is also an \( \epsilon \)-FOSP with \( [40] \)’s definition as well, but the reverse is not necessarily true.

### 2.2 Mirror-Prox

Mirror-Prox \( [34] \) is a popular algorithm proposed for solving convex-concave minimax problems \( (1) \). It achieves a convergence rate of \( O(1/k) \) for the primal dual gap. The original Mirror-Prox paper \( [34] \) motivates the algorithm through a conceptual Mirror-Prox (CMP) method, which brings out the main idea behind its convergence rate of \( O(1/k) \). CMP for Euclidean norm (after ignoring projections to \( \mathcal{X} \) and \( \mathcal{Y} \)) does the following update:

\[
(x_{k+1}, y_{k+1}) = (x_k, y_k) + \frac{1}{\beta} (\nabla_x g(x_{k+1}, y_{k+1}), \nabla_y g(x_{k+1}, y_{k+1})).
\]
The main difference between CMP and standard gradient descent ascent (GDA) is that in the \( k \)th step, while GDA uses gradients at \((x_k, y_k)\), CMP uses gradients at \((x_{k+1}, y_{k+1})\). The key observation of \cite{34} is that if \( g(\cdot, \cdot) \) is smooth, it can be implemented efficiently. CMP is analyzed as follows:

**Implementability of CMP:** Let \((x_k^{(0)}, y_k^{(0)}) = (x_k, y_k)\). For \( \beta < 1 \), the iteration

\[
(x_k^{(i+1)}, y_k^{(i+1)}) = (x_k, y_k) + \frac{1}{\beta} \left( -\nabla_x g \left( x_k^{(i)}, y_k^{(i)} \right) + \nabla_y g \left( x_k^{(i)}, y_k^{(i)} \right) \right).
\]

(6)

can be shown to be \( \frac{1}{\sqrt{\beta}} \)-contraction (when \( g(\cdot, \cdot) \) is smooth) and that its fixed point is \((x_{k+1}, y_{k+1})\). So, in \( \log \frac{1}{\beta} \) iterations of (6), we can obtain an accurate version of the update required by CMP. In fact, \cite{34} showed that just \( \log \frac{1}{\beta} \) iterations of (6) suffice \cite{30}.

**Convergence rate of CMP:** Using CMP update with simple manipulations leads to the following:

\[ g(x_{k+1}, y) - g(x, y_{k+1}) \leq \frac{\beta}{2} \left( \| x - x_k \|^2 - \| x - x_{k+1} \|^2 + \| y - y_k \|^2 - \| y - y_{k+1} \|^2 \right), \forall x \in \mathcal{X}, y \in \mathcal{Y}. \]

\( O(1/k) \) convergence rate follows easily using the above result.

Finally, our method and analysis also requires Nesterov’s accelerated gradient descent method (see Algorithm \cite{5} in Appendix A) and it’s per-step analysis by \cite{2} (Lemma \cite{2} in Appendix A).

### 3 Strongly-convex concave saddle point problem

We first study the minimax problem of the form:

\[
\min_{x \in \mathcal{X}} \left[ f(x) = \max_{y \in \mathcal{Y}} g(x, y) \right],
\]

(\text{P1})

where \( g(\cdot, \cdot) \) is concave, \( g(\cdot, \cdot) \) is \( \sigma \)-strongly-convex, \( g(\cdot, \cdot) \) is \( L \)-smooth, i.e., \( 0 < \sigma \leq L \), \( \mathcal{X} = \mathbb{R}^p \) and \( \mathcal{Y} \subseteq \mathbb{R}^q \) is a convex compact sub-set of \( \mathbb{R}^q \) and let the function \( f \) take a minimum value \( f^* (> -\infty) \). Let \( D_\mathcal{Y} = \max_{y \in \mathcal{Y}} \| y \| \) be the diameter of \( \mathcal{Y} \).

Our objective here is to find an \( \varepsilon \)-primal-dual pair \((\tilde{x}, \tilde{y})\) (see Definition \cite{2}). Now the fact that \( f(\tilde{x}) - f^* \leq \max_{y \in \mathcal{Y}} g(\tilde{x}, y) - \min_{x \in \mathcal{X}} g(x, \tilde{y}) \) implies that if \((\tilde{x}, \tilde{y})\) is an \( \varepsilon \)-primal-dual-pair, then \( \tilde{x} \) is also an \( \varepsilon \)-approximate minima of \( f \). Furthermore, by Sion’s minimax theorem \cite{24}, strong-convexity–concavity of \( g(\cdot, \cdot) \) ensures that: \( \min_x f(x) := \max_y g(x, y) = \max_y h(y) := \min_x g(x, y) \).

Hence, one approach to efficiently solving the problem is by optimizing the dual problem \( \max_y h(y) \).

By Lemma \cite{6} (in Appendix B.6), \( h(y) \) is an \( (L + \frac{L^2}{\sigma}) \)-smooth function. So we can use AGD to ensure that \( h(y_k) - h(y^*) = O(1/k^2) \). Now, each step of AGD requires computing \( \arg \min_x g(x, y_k) \) which can be done efficiently (i.e., logarithmic number of steps) as \( g(\cdot, y_k) \) is strongly-convex and smooth. So, the overall first-order oracle complexity is \( h(y_k) - h(y^*) = \tilde{O}(1/k^2) \).

So does this simple approach give us our desired result? Unfortunately not that is not the case, as the above bound on the dual function \( h \) does not translate to the same error rate for primal function \( f \), i.e., the solution need not be \( \tilde{O}(1/k^2) \)-primal-dual-pair. E.g., consider \( \min_{x \in \mathbb{R}} \max_{y \in [-1, 1]} |g(x, y) = xy + x^2/2| \), where \( \min_x \max_y g(x, y) = 0 \), \( f(x) = x^2/2 + |x| \) and \( h(y) = -y^2/2 \). If \( h(y_k) = \Theta(k^{-2}) \), then \( x_k \in \arg\min_x g(x, y_k) = \Theta(1/k) \) and so \( f(x_k) = \Theta(k^{-1}) \). This is due to the non-smoothness of \( \arg \max_{y \in \mathcal{Y}} g(x, y) \) w.r.t. \( x \).

Instead of using AGD, we introduce a new method to solve the dual problem that we refer to as DIAG, which stands for Dual Implicit Accelerated Gradient. DIAG combines ideas from AGD \cite{38} and Nemirovski’s original derivation of the Mirror-Prox algorithm \cite{24}, and can ensure a fast convergence rate of \( \tilde{O}(k^{-2}) \) for the primal-dual gap. We note that there also exists a conceptually simpler smoothing technique based indirect algorithm, which prefixes the tolerance of \( \varepsilon \) (Appendix D).

However, our goal is to find a direct algorithm which does note require prefixing the tolerance at \( \varepsilon \). For better exposition, we first present a conceptual version of DIAG (C-DIAG), which is not implemented exactly, but brings out the main new ideas in our algorithm. We then present a detailed error analysis for the inexact version of this algorithm, which is implementable.

#### 3.1 Conceptual version: C-DIAG

Consider the following updates which is a modified version of AGD (see Algorithm \cite{5} in Appendix A):
Algorithm 1 presents this inexact version. The following theorem states our formal result and a
we noted in the previous section, we can quickly find updates that almost satisfy the requirements.
where
\[ x_{k+1} \in \arg\min_x g(x, y_{k+1}), \text{ and } y_{k+1} = \mathcal{P}_Y(w_k + \frac{1}{\beta} \nabla_y g(x_{k+1}, w_k)) \]

(c) Choose \( x_{k+1}, y_{k+1} \) ensuring:
\[ z_{k+1} = \mathcal{P}_Y(z_k + \eta_k \nabla_y g(x_{k+1}, w_k)) \]

Complete pseudocode for C-DIAG algorithm is presented in Algorithm 2 in Appendix B.4. The main
idea of the algorithm is in Step (b) above (i.e., Step 4 of Algorithm 3 in Appendix A), where we simultanoulsy find \( x_{k+1} \) and \( y_{k+1} \) satisfying the following requirements:

- \( x_{k+1} \) is the minimizer of \( g(\cdot, y_{k+1}) \), and
- \( y_{k+1} \) corresponds to an AGD step (see Algorithm 2 in Appendix A) for \( g(x_{k+1}, \cdot) \)

**Implementability:** The first question is whether it is easy enough to implement such a step? It turns
out that it is indeed possible to quickly find points \( x_{k+1} \) and \( y_{k+1} \) that approximately satisfy the
above requirements. The reason is that:

- Since \( g(\cdot, y) \) is smooth and strongly convex for every \( y \in \mathcal{Y} \), we can find \( \epsilon \)-approximate
  minimizer for a given \( y \in O(\log \frac{1}{\epsilon}) \) iterations.
- Let \( x^*(y) := \arg\min_x g(x, y) \). The iteration \( y_{k+1}^{(i+1)} = \mathcal{P}_Y \left( w_k + \frac{1}{\beta} \nabla_y g(x^*(y^i), w_k) \right) \)
  is a 1/2-contraction with a unique fixed point satisfying the update step requirements (i.e., Step
  4 of Algorithm 3 in Appendix A). See Lemma 5 in Appendix B.5 for a proof. This means
  that only \( O(\log \frac{1}{\epsilon}) \) iterations again suffice to find an update that approximately satisfies the
  requirements.

**Convergence rate:** Since \( y_{k+1} \) and \( z_{k+1} \) correspond to an AGD update for \( g(x_{k+1}, \cdot) \), we can use the
potential function decrease argument for AGD (Lemma 1 in Appendix A) to conclude that \( \forall y \in \mathcal{Y} \):

\[
\begin{align*}
(k + 1)(k + 2) (g(x_{k+1}, y) - g(x_{k+1}, y_{k+1})) & \leq k + 1 (g(x_{k+1}, y) - g(x_{k+1}, y_{k})) + 2 \beta \cdot \|y - z_{k+1}\|^2 \\
& \leq k + 1 (g(x_{k+1}, y) - g(x_{k+1}, y_{k})) + 2 \beta \cdot \|y - z_k\|^2,
\end{align*}
\]

where the last step follows from the fact that \( x_k = \arg\min_x g(x, y_k) \) and so \( g(x_k, y_k) \leq g(x_{k+1}, y_k) \).

Noting that we can further recursively bound \( k + 1 (g(x_{k+1}, y) - g(x_{k+1}, y_{k})) + 2 \beta \cdot \|y - z_k\|^2 \) as
above, we obtain
\[
(\sum_{i=1}^{k+1} (2i) \cdot g(x, y) - (k + 1)(k + 2) g(x_{k+1}, y_{k+1}) \leq 2 \beta \cdot \|y - z_0\|^2.
\]
Since \( g(x_{k+1}, y_{k+1}) \leq g(x, y_{k+1}) \) for every \( x \in \mathcal{X} \), we have
\[
(\sum_{i=1}^{k+1} (2i) \cdot g(x, y) - (k + 1)(k + 2) g(x, y_{k+1}) \leq 2 \beta \cdot \|y - z_0\|^2.
\]

where \( \bar{x}_{k+1} := \frac{1}{(k+1)(k+2)} \sum_{i=1}^{k+1} (2i) \cdot x_i \). Since \( x \) and \( y \) are arbitrary above, this gives a \( O \left( 1/k^2 \right) \)
convergence rate for the primal dual gap.

### 3.2 Error analysis

The main issue with Algorithm 4 is that the update step is not exactly implementable. However, as
we noted in the previous section, we can quickly find updates that almost satisfy the requirements.
Algorithm 1 presents this inexact version. The following theorem states our formal result and a
detailed proof is provided in Appendix B.5.
Furthermore, for this setting the total first order oracle complexity is given by:

\[ O \] 

We study the nonconvex concave minimax problem (1) where \( f \) is concave, \( g \) is nonconvex, and \( \mathcal{X} = \mathbb{R}^p \) is a convex compact sub-set of \( \mathbb{R}^q \) (with diameter \( D_Y \)). Then, after \( K \) iterations, DIAG (Algorithm 1) with a tolerance schedule of \( \{\varepsilon_k\}_{k=1}^K \) for its Imp-STEP sub-routine, finds \((\hat{x}_K, y_K)\) s.t.: 

\[
\max_{y \in \mathcal{Y}} g(\hat{x}_K, y) - \min_{\hat{x} \in \mathcal{X}} g(\hat{x}, y_K) \leq \frac{4L^2 D_Y^2 + \sum_{k=1}^K k(k+1)\varepsilon_k}{K(K+1)}.
\] 

In particular, setting \( \varepsilon_k = \frac{L^2 D_Y^2}{\sigma^2 k(k+1)} \) we have: \( \max_{y \in \mathcal{Y}} g(\hat{x}_K, y) - \min_{\hat{x} \in \mathcal{X}} g(\hat{x}, y_K) \leq \frac{6L^2 D_Y^2}{\sigma^2 K(K+1)} \). Furthermore, for this setting the total first order oracle complexity is given by: \( O(\sqrt{\frac{\sigma^2}{\varepsilon}} K \log^2(K)) \).

**Remark 1:** Theorem 1 shows that DIAG needs \( \tilde{O}(D_Y L / \sqrt{\sigma \varepsilon}) \) gradient queries for finding a \( \varepsilon \)-primal-dual-pair, while current best-known rate is \( O(1/\varepsilon) \) achieved by Mirror-Prox. This dependence in \( \varepsilon \) and \( D_Y \) is optimal, as it is shown in [41]. Theorem 10 shows that \( \Omega(D_Y(L-\sigma)/\sqrt{\sigma \varepsilon}) \) gradient queries are necessary to achieve \( \varepsilon \) error in the primal-dual gap.

**Remark 2:** Unlike standard AGD for \( h(y) \), which only updates \( y_k \) in the outer-loop, DIAG’s outer-step updates both \( x_k \) and \( y_k \) thus allowing us to better track the primal-dual gap. However, DIAG’s dependence on the condition number \( L/\sigma \) seems sub-optimal and can perhaps be improved if we do not compute Imp-STEP nearly optimally allowing for inexact updates; we leave further investigation into improved dependence on the condition number for future work.

### 4 Nonconvex concave saddle point problem

We study the nonconvex concave minimax problem (1) where \( g(x, \cdot) \) is concave, \( g(\cdot, y) \) is nonconvex, and \( f(\cdot, \cdot) \) is \( L \)-smooth, \( \mathcal{X} = \mathbb{R}^p \) (such that \( \text{Proj}_{\mathcal{X}}(x) = x \)) and \( \mathcal{Y} \) is a convex compact sub-set of \( \mathbb{R}^q \). As mentioned in Section 2, we measure the convergence to an approximate FOSP of this problem (see Definition 3) but it requires weak-convexity of \( f(x) := \max_{y \in \mathcal{Y}} g(x, y) \). The following lemma guarantees weak convexity of \( f \) given smoothness of \( g \).
Lemma 1. Let \( g(\cdot, y) \) be continuous and \( \mathcal{Y} \) be compact. Then \( f(x) = \max_{y \in \mathcal{Y}} g(x, y) \) is L-weakly convex, if \( g \) is L-weakly convex in \( x \) (Definition 7), or if \( g \) is L-smooth in \( x \).

See Appendix B.3 for the proof. The arguments of [18] easily extend to show that applying subgradient method on \( f(x) \), [11] gives a convergence rate of \( O \left( \frac{1}{k^{1/5}} \right) \). Instead, we exploit the smooth minimax form of \( f(\cdot) \) to design a faster converging scheme. The main intuition comes from the proximal viewpoint that gradient descent can be viewed as iteratively forming and optimizing local quadratic upper bounds. As \( f \) is weakly convex, adding enough quadratic regularization should ensure that the resulting sequence of problems are all strongly-convex–concave. We then exploit DIAG to efficiently solve such local quadratic problems to obtain improved convergence rates. Concretely, let

\[
\hat{f}(x; x_k) = \max_y g(x, y) + L\|x - x_k\|^2.
\]

(9)

By L-weak-convexity of \( f \), \( \hat{f}(x; x_k) \) is strongly-convex–concave (Lemma 3) that can be solved using DIAG up to certain accuracy to obtain \( x_{k+1} \). We refer to this algorithm as Prox-DIAG and provide a pseudo-code for the same in Algorithm 2. The following theorem gives convergence guarantees for Prox-DIAG.

**Theorem 2** (Convergence rate of Prox-DIAG). Let \( g(x, y) \) be L-smooth, \( g(x, \cdot) \) be concave, \( \mathcal{X} \) be \( \mathbb{R}^p \), \( \mathcal{Y} \) be a convex compact subset of \( \mathbb{R}^q \), and the minimum value of function \( f(x) = \max_{y \in \mathcal{Y}} g(x, y) \) be bounded below, i.e. \( f(x) \geq f^* > -\infty \). Then Prox-DIAG (Algorithm 2) after

\[
K = \left\lfloor \frac{4^4 L^2 D_{\mathcal{Y}}(f(x_0) - f^*)}{3 \varepsilon^2} \log^2 \left( \frac{1}{\varepsilon} \right) \right\rfloor
\]

steps outputs an \( \varepsilon \)-FOSP. The total first-order oracle complexity to output \( \varepsilon \)-FOSP is:

\[
O \left( \frac{L^2 D_{\mathcal{Y}}(f(x_0) - f^*)}{\varepsilon^3} \log^2 \left( \frac{1}{\varepsilon} \right) \right).
\]

A proof is provided in Appendix B.7. Note that Prox-DIAG solves the quadratic approximation problem to higher accuracy of \( O(\varepsilon^2) \) which then helps bounding the gradient of the Moreau envelope. Also due to the modular structure of the argument, a faster inner loop for special settings, e.g., when \( g(x, y) \) is a finite-sum, can ensure more efficient algorithm. While our algorithm is able to significantly improve upon existing state-of-the-art rate of \( O(1/\varepsilon^5) \) in general nonconvex-concave setting [13], it is unclear if the rate can be further improved. In fact, precise lower-bounds for this setting are mostly unexplored and we leave further investigation into lower-bounds as a topic of future research.

We also specialize the Prox-DIAG algorithm, as Prox-FDIAG (Algorithm 5 in Appendix C), for the case of minimizing a weakly convex \( f(x) \), with the special structure of finite max-type function:

\[
\min_{x} \left[ f(x) = \max_{1 \leq i \leq m} f_i(x) \right],
\]

(P3)
where \( f_i \)'s could be nonconvex but are \( L \)-smooth, \( G \)-Lipschitz and bounded from below. For this case, we improve the current known best rate of \( O\left( \frac{m}{\varepsilon^4} \right) \) and obtain a faster rate of \( O\left( \frac{m \log^{3/2}}{m/\varepsilon^3} \right) \) using the Prox-FDIAG algorithm. Please refer to Appendix C for more details.

5 Experiments

We empirically verify the performance of Prox-FDIAG (Algorithm 5 in Appendix C) on a synthetic finite max-type nonconvex minimization problem (P3). We consider the following problem.

\[
\min_{x \in \mathbb{R}^2} \left[ f(x) = \max_{1 \leq i \leq m=9} f_i(x) \right]
\]

where \( f_i(x) = q_{(a,b,c)}(x) = \|x - b\|_2^2 + c, X_i^{(1)}, X_i^{(2)} \), and \( c_i \) are randomly generated. Thus each \( f_i \) is smooth with parameter \( L = 1 \), which implies that \( f \) is \( L \)-weakly convex. We implement three algorithms: Prox-FDIAG (Algorithm 5 red circles), Adaptive Prox-FDIAG (Algorithm 6 black dots), and subgradient method [11] (blue triangles). Adaptive Prox-FDIAG is a practically faster variant of Prox-FDIAG, with the same first-order oracle complexity guarantee (up to an \( O(\log(1/\varepsilon)) \) factor).

In Figure 1, we plot the norm of gradient of Moreau envelope \( \|\nabla f_{\pi}(x_k)\|_2 \) against the number of iterations \( k \) in log-log scale. We see that, Prox-FDIAG and Adaptive Prox-FDIAG have a faster convergence rate than subgradient method, and Adaptive Prox-FDIAG is almost always faster than Prox-FDIAG. We provide more details about the algorithms and the experiments in Appendix E.

6 Conclusion

In this paper, we study smooth minimax problems, where the maximization is concave but the minimization is either strongly convex or nonconvex. In both of these settings, we present new algorithms improving state-of-the-art. The key ideas are i) a novel way to combine Mirror-Prox and Nesterov’s AGD for strongly convex case that can tightly bound primal-dual gap and ii) an inexact prox method with good convergence rate to stationary points for the nonconvex case. While we only present our results for the Euclidean setting, generalizing it to non-Euclidean settings with the framework of Bregman divergences should be straightforward. Finally, we showcase the empirical superiority of our nonconvex algorithm over state-of-the-art subgradient method for a case of finite max-type nonconvex minimization problems. Some of the more interesting questions would be to understand the optimality of the rates that we obtain and dependence on the strong convexity parameter. Further extensions of these results to the stochastic setting would also be quite interesting.

Appendix

A Nesterov’s accelerated gradient descent

**Algorithm 3: Nesterov’s accelerated gradient ascent**

| Input: Smooth concave function $h(\cdot)$, learning rate $\frac{1}{\beta}$, initial points $y_0$ and $z_0$ |
| Output: $y_k$ |
| for $k = 0, 1, \ldots$ do |
| $w_k \leftarrow (1 - \tau_k)y_k + \tau_k z_k$, $y_{k+1} \leftarrow \mathcal{P}_Y \left( w_k + \frac{1}{\beta} \nabla h(w_k) \right)$, |
| $z_{k+1} \leftarrow \mathcal{P}_Y \left( z_k + \eta_k \nabla h(w_k) \right)$ |

Nesterov’s accelerated gradient descent [38] is an optimal method for minimizing smooth convex functions (or equivalently maximizing smooth concave functions). In order to simplify the exposition in the sequel, we will consider the algorithm for maximizing concave functions. The pseudocode for this is presented in Algorithm [3] Here $\mathcal{P}_Y(\cdot)$ denotes projection onto $\mathcal{Y}$.

A.1 Smooth concave function

Consider the potential function

$$\Phi(k) := k(k+1)(h(y) - h(y_k)) + 2\beta \cdot \|y - z_k\|^2.$$ 

The following lemma (from [2]) is the key result that helps us obtain the convergence rate of Algorithm 3. Here $\mathcal{P}_Y(\cdot)$ denotes projection onto $\mathcal{Y}$.

**Lemma 2.** Suppose $h(\cdot)$ is an $L$-smooth concave function and the parameters of Algorithm 3 are chosen so that $\beta > L$. $\eta_k = \frac{k+1}{2\beta}$ and $\tau_k = \frac{2}{k+2}$. Then, we have

$$\Phi(k+1) \leq \Phi(k).$$

**Proof of Lemma 2** Writing

$$\Phi(k+1) - \Phi(k) = (k+1)(k+2)(h(w_k) - h(y_{k+1}))$$

$$- k(k+1)(h(w_k) - h(y_k)) + 2(k+1)(h(y) - h(w_k))$$

$$+ 2\beta (\|z_{k+1} - y\|^2 - \|z_k - y\|^2),$$

we bound the three terms appearing in separate lines above. Firstly, for the third term, $\|z_{k+1} - y\|^2 \leq \|z_k + \eta_k \nabla h(w_k) - y\|^2 - \|z_{k+1} - z_k - \eta_k \nabla h(w_k)\|^2$ due to Pythagoras theorem and so

$$\|z_{k+1} - y\|^2 - \|z_k - y\|^2 \leq 2\eta_k \langle \nabla h(w_k), z_k - y \rangle + \eta_k^2 \|\nabla h(w_k)\|^2 - \|z_{k+1} - z_k - \eta_k \nabla h(w_k)\|^2$$

$$\leq 2\eta_k \langle \nabla h(w_k), z_{k+1} - y \rangle - \|z_{k+1} - z_k\|^2.$$  

(14)

For the second term, we have

$$- k(k+1)(h(w_k) - h(y_k)) + 2(k+1)(h(y) - h(w_k))$$

$$\leq -k(k+1)\langle \nabla h(w_k), w_k - y_k \rangle + 2(k+1)\langle \nabla h(w_k), y - w_k \rangle = 2(k+1)\langle \nabla h(w_k), y - z_k \rangle.$$  

(15)

Finally, for the first term, we have $h(y_{k+1}) - h(y_k) \geq \langle \nabla h(w_k), y_{k+1} - w_k \rangle - \frac{\beta}{2} \|y_{k+1} - w_k\|^2$. Since $y_{k+1} = \arg \max_{y \in \mathcal{Y}} \langle \nabla h(w_k), y - w_k \rangle - \frac{\beta}{2} \|y - w_k\|^2$, we have for $v := (1 - \tau_k)y_k + \tau_k z_{k+1} \in \mathcal{Y}$,

$$h(y_{k+1}) - h(w_k) \geq \langle \nabla h(w_k), y_{k+1} - w_k \rangle - \frac{\beta}{2} \|y_{k+1} - w_k\|^2$$

$$\geq \langle \nabla h(w_k), v - w_k \rangle - \frac{\beta}{2} \|v - w_k\|^2 = \tau_k \langle \nabla h(w_k), z_{k+1} - z_k \rangle - \frac{\beta \tau_k^2}{2} \|z_{k+1} - z_k\|^2,$$  

(16)

where we used $w_k = (1 - \tau_k)y_k + \tau_k z_k$ in the last step. Substituting (16), (15) and (14) in (13) proves the lemma. \qed
B Proofs

B.1 Auxiliary lemma

**Lemma 3.** If \( f(x) \) is a L-weakly convex function and \( \tilde{f}(x) \) is a \( \tilde{\sigma}(\geq L) \)-strongly convex differentiable function, then \( f(x) + \tilde{f}(x) \) is \( (\tilde{\sigma} - L) \)-strongly convex.

**Proof.** Since \( f \) is L-weakly convex and \( \tilde{f} \) is \( \sigma \)-strongly convex we get that,

\[
f(x') \geq f(x) + \langle u_x, x' - x \rangle - \frac{L}{2} \| x' - x \|^2,
\]

\[
\frac{\tilde{f}(x')}{\tilde{f}(x)} \geq \frac{\tilde{f}(x)}{\tilde{f}(x)} + \langle \nabla \tilde{f}(x), x' - x \rangle + \frac{\tilde{\sigma}}{2} \| x' - x \|^2,
\]

\[
\implies f(x') + \tilde{f}(x') \geq f(x) + \tilde{f}(x) + \langle u_x + \nabla \tilde{f}(x), x' - x \rangle + \frac{\tilde{\sigma} - L}{2} \| x' - x \|^2.
\]

where \( u_x \in \partial f(x) \). We finish the proof by noting that \( \partial(f + \tilde{f}) = \partial f + \nabla \tilde{f} \) [27] Corollary 1.12.2.\)

B.2 Properties of Moreau envelope

The following lemma provides some useful properties of the Moreau envelope for weakly convex functions.

**Lemma 4.** For an L-weakly convex proper l.s.c. function \( f : \mathcal{X} \to \mathbb{R} \cup \{\infty\} \) such that \( \mathcal{X} = \mathbb{R}^p \) and \( L < 1/\lambda \), the following hold true.

(a) The minimizer \( \hat{x}_\lambda(x) = \arg \min_{x' \in \mathcal{X}} f(x') + \frac{1}{2\lambda} \| x - x' \|^2 \) is unique and \( f(\hat{x}_\lambda(x)) \leq f(x) \). Furthermore, \( \arg \min_x f(x) = \arg \min_x f(\hat{x}_\lambda(x)) \).

(b) \( f_\lambda \) is \( (\frac{1}{\lambda} + \frac{1}{2\lambda(1-\lambda L)}) \)-smooth and thus differentiable, and

(c) \( \min_{u \in \partial f(\hat{x}_\lambda(x))} \| u \| \leq (1/\lambda) \| \hat{x}_\lambda(x) - x \| = \| \nabla f(\hat{x}_\lambda(x)) \| \).

**Proof.** We re-write \( f_\lambda(x) \) as minimum value of a \((\frac{1}{\lambda} - L)\)-strong convex function \( \phi_{\lambda,x} \), as \( f \) is L-weakly convex (Definition 1) and \( \frac{1}{2\lambda} \| x - x' \|^2 \) is differentiable and \( \frac{1}{\lambda} \)-strongly convex (Lemma 3),

\[
f_\lambda(x) = \min_{x' \in \mathcal{X}} \left[ \phi_{\lambda,x}(x') = f(x') + \frac{1}{2\lambda} \| x - x' \|^2 \right].
\]

Then first part of (a) follows trivially by the strong convexity. For the second part notice the following,

\[
\min_x f_\lambda(x) = \min_x \min_{x'} f(x') + \frac{1}{2\lambda} \| x - x' \|^2
\]

\[
= \min_{x'} \min_x f(x') + \frac{1}{2\lambda} \| x - x' \|^2
\]

\[
= \min_{x'} f(x')
\]

Thus \( \arg \min_x f_\lambda(x) = \arg \min_x f(x) \). For (b) we can re-write the Moreau envelope \( f_\lambda \) as,

\[
f_\lambda(x) = \min_{x'} f(x') + \frac{1}{2\lambda} \| x - x' \|^2
\]

\[
= \| x \|^2 - \frac{1}{2\lambda} \left[ \frac{1}{\lambda} \max_{x'} (x^T x' - \lambda f(x') - \| x' \|^2) \right]
\]

\[
= \| x \|^2 - \frac{1}{2\lambda} \left( \lambda f(\cdot) + \frac{\| \cdot \|^2}{2} \right)^\ast(x)
\]

where \( (\cdot)^\ast \) is the Fenchel conjugation operator. Since \( L < 1/\lambda \), using \( L \)-weak convexity of \( f \), it is easy to see that \( \lambda f(x') + \frac{\| x' \|^2}{2} \) is \((1 - \lambda L)\)-strongly convex, therefore its Fenchel conjugate would
be $\frac{1}{(1-\lambda L)}$-smooth [21] Theorem 6]. This, along with $\frac{1}{\lambda}$-smoothness of first quadratic term implies that $f_\lambda(x)$ is $(\frac{1}{\lambda} + \frac{1}{(1-\lambda L)})$-smooth, and thus differentiable.

For (c) we again use the reformulation of $f_\lambda(x)$ as $\min_{x'\in X} \phi_{\lambda,x}(x')$ (18). Then by first-order necessary condition for optimality of $\hat{x}_\lambda(x)$, we have that $x - \hat{x}_\lambda(x) \in \lambda \partial f(x)$. Further, from proof of part (a) we have that $\phi_{\lambda,x}(x')$ $(1-\lambda L)$-strongly-convex in $x'$ and it is quadratic (and thus convex) in $x$. Then we can use Danskin’s theorem [4] Section 6.11] to prove that, $\nabla f_\lambda(x) = (x - \hat{x}_\lambda(x))/\lambda \in \partial f(x)$. Refer [43] Section B.1] for other proofs of the same result.

\[ \square \]

\section*{B.3 Proof of Lemma 1}

It is easy to see that $g(\cdot, y)$ is $L$-weakly convex if it is $L$-smooth: $g(x', y) \geq g(x, y) + \langle \nabla_x g(x, y), x' - x \rangle - \frac{L}{2} \|x' - x\|^2$. Thus we only need to prove the case of $L$-weakly convex $g(\cdot, y)$. Since $g(\cdot, y)$ is $L$-weakly convex we get that,

$$g(x', y) \geq g(x, y) + \langle u_{x,y}, x' - x \rangle - \frac{L}{2} \|x' - x\|^2$$

\[ \implies g(x', y) + \frac{L}{2} \|x'\|^2 \geq g(x, y) + \frac{L}{2} \|x\|^2 + (u_{x,y} + Lx, x' - x) \]

where $u_{x,y} \in \partial_x g(x, y)$. This means that $\tilde{g}(x, y) := g(x, y) + \frac{L}{2} \|x\|^2$ is convex, since $\partial_x \tilde{g}(x, y) = \partial_x g(x, y) + Lx$ [27 Corollary 1.12.2].

Let $\hat{f}(x) = \max_{y \in Y} \tilde{g}(x, y)$. Since $\tilde{g}(x, y)$ is convex in $x$ and smooth (Definition 1), and $Y$ is compact set we use Danskin’s theorem [4] Section 6.11] to prove that,

$$\partial \hat{f}(x) = \text{conv}\{\partial_x \tilde{g}(x, y^*) | y^* \in \arg \max_{y \in Y} \tilde{g}(x, y)\},$$

\[ \implies \partial f(x) = \text{conv}\{\partial_x g(x, y^*) + Lx | y^* \in \arg \max_{y \in Y} g(x, y)\}, \]

\[ \implies \partial f(x) = \text{conv}\{\partial_x g(x, y^*) | y^* \in \arg \max_{y \in Y} g(x, y)\}. \] (20)

where the second to last step comes from the facts that $\partial \hat{f} = \partial f + Lx$, $\partial_x \tilde{g}(x, y) = \partial_x g(x, y) + Lx$ [27 Corollary 1.12.2], and $\arg \max_{y \in Y} \tilde{g}(x, y) = \arg \max_{y \in Y} g(x, y)$. Let $u_{x,y} \in \partial_x g(x, y)$ and $y^* \in \arg \max_{y \in Y} g(x, y)$ then,

$$f(x') \geq g(x', y^*) \geq g(x, y^*) + \langle u_{x,y}, x' - x \rangle - \frac{L}{2} \|x' - x\|^2$$

\[ \implies (a) \implies f(x') \geq f(x) + \langle v_x, x' - x \rangle - \frac{L}{2} \|x' - x\|^2 \]

where $(a)$ uses $L$-weak convexity of $g(\cdot, y)$, and $(b)$ uses \[20\] and $v_x \in \partial f(x)$.

\section*{B.4 Pseudocode for Conceptual DIAG algorithm}

The pseudocode for C-DIAG algorithm is presented in Algorithm [4].

\section*{B.5 Proof of Theorem 1}

A cursory glance of the DIAG (Algorithm 1) reveals that it is a modified version of projected accelerated gradient ascent (Algorithm 3) on some function of $y$ with a modified step given by Imp–STEP, which is inspired from the conceptual Mirror-Prox method of [34]. In the following lemma we analyze the Imp–STEP sub-routine, which is the most non-trivial step of the algorithm.

\textbf{Lemma 5.} If $\beta = 2\frac{L^2}{\sigma}$, the sub-routine Imp–STEP($g, L, \sigma, w, \beta, \varepsilon_{\text{step}}$) of Algorithm 1 returns a pair of points $(\hat{x}_{R'}, y_{R+1}) \in X \times Y$, such that,

$$g(\hat{x}_{R'}, y_{R+1}) \leq \min_x g(x, y_R) + \varepsilon_{\text{step}}, \quad \text{and}, \quad y_R = \mathcal{P}_Y \left( w + \frac{1}{\beta} \nabla_y g(\hat{x}_{R-1}, w) \right)$$

\begin{equation}
R = \lceil \log_2 \left( \left( 5LD_Y / \sigma \right) \sqrt{L/2\varepsilon_{\text{step}}} \right) \rceil \quad \text{iterations with } O \left( \sqrt{L/\sigma} \log \left( 1/\varepsilon_{\text{step}} \right) \right) \text{ gradient computations per iterations.}
\end{equation}
Algorithm 4: Conceptual Dual Implicit Accelerated Gradient (C-DIAG) for strongly-convex–concave programming

**Input:** $g, L, \sigma, x_0, y_0, K$

**Output:** $\bar{x}_K, y_K$

1. Set $\beta \leftarrow \frac{2L^2}{\sigma^2}$, $z_0 \leftarrow y_0$

2. for $k = 0, 1, \ldots, K - 1$ do

3. $\tau_k \leftarrow \frac{2}{(k+2)}, \quad \eta_k \leftarrow \frac{(k+1)}{2\beta}$, $w_k \leftarrow (1 - \tau_k)y_k + \tau_kz_k$

4. Choose $x_{k+1}, y_{k+1}$ ensuring:

   $g(x_{k+1}, y_{k+1}) = \min_x g(x, y_{k+1})$, $y_{k+1} = \mathcal{P}_Y \left( w_k + \frac{1}{\beta} \nabla_y g(x_{k+1}, w_k) \right)$

5. $z_{k+1} \leftarrow \mathcal{P}_Y \left( z_k + \eta_k \nabla_y g(x_{k+1}, w_k) \right)$, $\bar{x}_{k+1} \leftarrow \frac{2}{(k+1)(k+2)} \sum_{i=1}^{k+1} i \cdot x_i$

6. return $\bar{x}_K, y_K$

A proof for this lemma is provided in Appendix B.5.1. The above lemma guarantees that the Imp-STEP sub-routine converges fast (linear time), in $O(\log(1/\epsilon_{\text{step}}))$ steps with $O(\sqrt{L/\sigma} \log(2(1/\epsilon_{\text{step}})))$ number of gradient computations.

In the rest of the proof we will utilize the recently proposed potential-function based proof for accelerated gradient decent (AGD) [2, Section 5.2]. Analyzing AGD using potential-function has an advantage over the standard analysis because, even though AGD does not decrease the function value monotonically the former constructs a potential-function which monotonically decreases over the iterations. Given the guarantees (Lemma 5) for the Imp-STEP sub-routine we can re-write an iteration of the DIAG algorithm by the following steps:

\begin{align}
\tau_k &= \frac{2}{(k+2)}, \quad \eta_k = \frac{(k+1)}{2\beta} \\
w_k &= (1 - \tau_k)y_k + \tau_kz_k \tag{22} \\
y_{k+1} &= \mathcal{P}_Y \left( w_k + \frac{1}{\beta} \nabla_y h_{x_{k+1}}(w_k) \right) \tag{23} \\
z_{k+1} &= \mathcal{P}_Y \left( z_k + \eta_k \nabla_y h_{x_{k+1}}(w_k) \right) \tag{24}
\end{align}

where $h_{x_{k+1}}(y) := g(x_{k+1}, y)$ such that $g(x_{k+1}, y_{k+1}) \leq \min_{x \in \mathcal{X}} g(x, y_{k+1}) + \epsilon_{\text{step}}$. That is at iteration $k$, DIAG executes the $k$-th step of the accelerated gradient ascent for the concave function $h_{x_{k+1}} = g(x_{k+1}, \cdot)$ (Algorithm 3). As in (12), for the concave function $h_k : \mathcal{Y} \rightarrow \mathbb{R}$ and an arbitrary reference point $\tilde{y} \in \mathcal{Y}$, we define the following potential function for iteration $j$,

$$
\Phi^{h_k}(j) = j(j+1)(h_k(\tilde{y}) - h_k(y_j)) + 2\beta||z_j - \tilde{y}||^2 \tag{26}
$$

Since $g(x, \cdot)$ is $L$-smooth, it is also $\frac{2L^2}{\sigma}$-smooth ($\sigma \leq L$). Then, using Lemma 2, we see that for a step-size of $\frac{1}{\beta} = \frac{\sigma}{2L^2}$, the potential function $\Phi^{h_k}(k)$ decrease at step of $k$ of the algorithm:
\[ \Phi^{h_{k+1}}(k+1) \leq \Phi^{h_{k+1}}(k). \] Thus,
\[ \Phi^{h_{k+1}}(k+1) \leq \Phi^{h_{k+1}}(k) \]
\[ = k(k+1)(h_{k+1}(\tilde{y}) - h_{k+1}(y_k)) + 2\beta \| z_k - \tilde{y} \|^2 \]
\[ = k(k+1)(h_{k}(\tilde{y}) - h_{k}(y_k)) + 2\beta \| z_k - \tilde{y} \|^2 + \]
\[ k(k+1)(h_{k+1}(\tilde{y}) - h_{k}(\tilde{y})) + k(k+1)(h_{k}(y_k) - h_{k+1}(y_k)) \]
\[ = \Phi^{h_k}(k) + k(k+1)(g(x_{k+1}, \tilde{y}) - g(x_k, \tilde{y})) + k(k+1)(g(x_k, y_k) - g(x_{k+1}, y_k)) \]
\[ \leq \Phi^{h_k}(k) + k(k+1)(g(x_{k+1}, \tilde{y}) - g(x_k, \tilde{y})) + k(k+1)\varepsilon_{\text{step}}^{(k)} \quad (27) \]
\[ \Rightarrow (b) \quad \Phi^{h_k}(K) \leq \Phi^{h_0}(0) + \sum_{k=0}^{K-1} k(k+1)(g(x_{k+1}, \tilde{y}) - g(x_k, \tilde{y})) + \sum_{k=1}^{K-1} k(k+1)\varepsilon_{\text{step}}^{(k)} \]
\[ \leq \Phi^{h_0}(0) + (K-1)Kg(x_K, \tilde{y}) - \sum_{k=1}^{K-1} 2k g(x_k, \tilde{y}) + \sum_{k=1}^{K-1} k(k+1)\varepsilon_{\text{step}}^{(k)} \quad (28) \]

Where (a) follows from Lemma 5 and \( g(x_k, y_k) - g(x_{k+1}, y_k) \leq g(x_k, y_k) - \min_x g(x, y_k) \leq \varepsilon_{\text{step}}^{(k)} \).

(b) is obtained summing (27) over \( k = \{0, \ldots, K-1\} \). Rearranging the terms of (28) we get,
\[ \Phi^{h_0}(0) + \sum_{k=1}^{K-1} k(k+1)\varepsilon_{\text{step}}^{(k)} \geq \sum_{k=1}^{K-1} 2k g(x_k, \tilde{y}) + \Phi^{h_k}(K) - (K-1)Kg(x_K, \tilde{y}) \]
\[ \geq \sum_{k=1}^{K-1} 2k g(x_k, \tilde{y}) + K(K+1)(g(x_K, \tilde{y}) - g(x_k, y_k)) + \]
\[ 2\beta \| z_k - \tilde{y} \|^2 - (K-1)Kg(x_K, \tilde{y}) \]
\[ \geq \sum_{k=1}^{K} 2k g(x_k, \tilde{y}) - K(K+1)g(x_k, y_k) \]
\[ \geq K(K+1)[g(x_K, \tilde{y}) - g(x_k, y_k)] \]
\[ \geq K(K+1)[g(\bar{x}_K, \tilde{y}) - g(\bar{x}, y_k) - \varepsilon_{\text{step}}^{(k)}] \quad (29) \]

where (a) uses the \( \bar{x}_K = \frac{1}{K(K+1)} \sum_{k=1}^{K} (2i) x_i \) and convexity of \( g(\cdot, \tilde{y}) \), and (b) uses Lemma 6. Thus we get that,
\[ g(\bar{x}_K, \tilde{y}) - g(\bar{x}, y_k) \leq \frac{\Phi^{h_0}(0)}{K(K+1)} + \sum_{k=1}^{K} \frac{k(k+1)}{K(K+1)}\varepsilon_{\text{step}}^{(k)} \]
\[ = \frac{2\beta \| y_0 - \tilde{y} \|^2}{K(K+1)} + \sum_{k=1}^{K} \frac{k(k+1)}{K(K+1)}\varepsilon_{\text{step}}^{(k)} \quad (30) \]

Finally we get the desired general statement by taking minimum and maximum over \( \bar{x} \) and \( \tilde{y} \) respectively. By selecting \( \varepsilon_{\text{step}}^{(k)} = \frac{L^2 D_{\tilde{y}}^2}{\sigma k(K+1)} \) we get,
\[ \max_{\bar{x} \in X} g(\bar{x}_K, \tilde{y}) - \min_{\bar{x} \in X} g(\bar{x}, y_k) \leq \frac{6L^2 D_{\tilde{y}}^2}{K(K+1)} \quad (31) \]

Further, using Lemma 5 and \( \varepsilon_{\text{step}}^{(k)} = \frac{L^2 D_{\tilde{y}}^2}{\sigma k(K+1)} \), we get that the total number of gradient computations at iteration \( k \) is at most \( O\left(\sqrt{\frac{L}{\sigma}} \log^2 (k^4)\right) \):
\[ \left[ \log_2 5k^2 \sqrt{\frac{L}{\sigma}} \middle] O\left(\sqrt{\frac{L}{\sigma}} \log (k^4)\right) \quad (32) \]

Note that in updating \( y_{k+1} \) in Eq. (24) and \( x_{k+1} \) in Imp-STEP sub-routine, we were applying the principle of conceptual Mirror-Prox, where the update needs to satisfy some fixed point equation. This is critical in proving the above fast convergence rate.
B.5.1 Proof of Lemma 5

For brevity, we define the following operations,

\[ x^*(y) = \arg \min_{x \in \mathcal{X}} g(x, y) \]  

(33)

\[ y^+ = \mathcal{P}_\mathcal{Y} \left( w + \frac{1}{\beta} \nabla_y g(x^*(y), w) \right) \]  

(34)

\( x^*(y) \) is unique since \( g(\cdot, y) \) is strongly convex. We first prove that, \( x^*(y) \) is \( \frac{\beta}{\sigma} \)-Lipschitz continuous as follows.

\[
\sigma \| x^*(y_2) - x^*(y_1) \|^2 \leq \begin{cases} 
(\nabla_x g(x^*(y_2), y_2) - \nabla_x g(x^*(y_1), y_2), x^*(y_2) - x^*(y_1)) \\
(\nabla_x g(x^*(y_1), y_1) - \nabla_x g(x^*(y_1), y_2), x^*(y_2) - x^*(y_1)) \\
L \| y_1 - y_2 \| | x^*(y_2) - x^*(y_1) | 
\end{cases} \]  

(35)

where (a) uses \( \sigma \)-strong convexity of \( g(\cdot, y) \), (b) uses the necessary first order optimality conditions for \( x^*(y_1) \) and \( x^*(y_2) \); (c) uses Cauchy-Schwarz inequality and \( L \)-smoothness of \( g \) (Definition 1). Next we prove that the operation \( (\cdot)^+ \) is a contraction as follows,

\[
\| y_1^+ - y_2^+ \| = \| \mathcal{P}_\mathcal{Y} \left( w + \frac{1}{\beta} \nabla_y g(x^*(y_1), w) \right) - \mathcal{P}_\mathcal{Y} \left( w + \frac{1}{\beta} \nabla_y g(x^*(y_2), w) \right) \| \\
\leq \begin{cases} 
\frac{1}{\beta} \| \nabla_y g(x^*(y_1), w) - \nabla_y g(x^*(y_2), w) \| \\
L \| y_1 - y_2 \| | x^*(y_1) - x^*(y_2) | \\
L \frac{\beta}{\sigma} \| y_1 - y_2 \| \leq 2^{-1} \| y_1 - y_2 \| \end{cases} \]  

(36)

where (a) uses Pythagorean theorem and \( \nabla_y g \), (b) uses \( L \)-smoothness of \( g \), (c) uses \( \| y_1 - y_2 \| \leq 2^{-1} \| y_1 - y_2 \| \) and \( x^*(y_1) - x^*(y_2) \) uses \( \frac{\beta}{\sigma} \)-Lipschitz continuity of \( \mathcal{P}_\mathcal{Y} \). Now we will prove that the output of \( \text{Imp-STEP} \) satisfies \( (\hat{x}_R, \hat{y}_{R+1}) \) satisfies (21). Notice that if \( \varepsilon_{aga} \) is small then \( \hat{x}_r \) is close to \( x^*(y_r) \):

\[
\frac{\sigma}{2} \| \hat{x}_r - x^*(y_r) \|^2 \leq g(\hat{x}_r, y_r) - \min_{x} g(x, y_r) \Rightarrow \| \hat{x}_r - x^*(y_r) \| \leq \sqrt{\frac{2\varepsilon_{aga}}{\sigma}} = \frac{\beta \varepsilon_{mp}}{4L} \]  

(37)

where (a) uses \( \sigma \)-strong convexity and optimality of \( x^*(y_r) \), and (b) uses (7), and (c) uses \( \varepsilon_{aga} = \sigma \beta^2 \varepsilon_{mp}/(32L^2) \). Next we see that \( \| y_r - \hat{y} \| \) decreases to \( \varepsilon \) exponentially fast.

\[
\| y_r - \hat{y} \| \leq \begin{cases} 
\| \mathcal{P}_\mathcal{Y} \left( w + \frac{1}{\beta} \nabla_y g(\hat{x}_{r-1}, w) \right) - (\hat{y})^+ \| \\
\| y_{r-1}^+ - (\hat{y})^+ \| + \| \mathcal{P}_\mathcal{Y} \left( w + \frac{1}{\beta} \nabla_y g(x^*(y_{r-1}), w) \right) - \mathcal{P}_\mathcal{Y} \left( w + \frac{1}{\beta} \nabla_y g(\hat{x}_{r-1}, w) \right) \| \\
2^{-1} \| y_{r-1} - \hat{y} \| + \frac{L}{\beta} \| x^*(y_{r-1}) - \hat{x}_{r-1} \| \\
2^{-1} \| y_{r-1} - \hat{y} \| + \frac{\varepsilon_{mp}}{4} \\
2^{-r} \| y_0 - \hat{y} \| + \frac{\varepsilon_{mp}}{2} \end{cases} \]  

(38)

where (a) uses \( y_{r+1} = \mathcal{P}_\mathcal{Y} \left( w + \frac{1}{\beta} \nabla_y g(\hat{x}_r, w) \right) \) and the fact that \( \hat{y} = (\hat{y})^+ \) is a fixed point, (b) uses triangular inequality and (34), (c) uses (36), Pythagorean theorem and \( L \)-smoothness of \( g \).
\[(\text{Definition 1}), \text{ (d) uses (37), and (e) just unrolls the recurrence relation in (38)}. \text{ Next, we prove that the minimizer at } y_{R+1}, x^*(y_{R+1}) \text{ is not far from } \hat{x}_R.\]

\[
\|x^*(y_{R+1}) - \hat{x}_R\| \leq \|x^*(y_{R+1}) - x^*(\hat{y})\| + \|x^*(\hat{y}) - x^*(y_R)\| + \|x^*(y_R) - \hat{x}_R\|
\]

\[
\leq \frac{L}{\sigma} (\|y_{R+1} - \hat{y}\| + \|y_R - \hat{y}\|) + \frac{\beta \varepsilon_{mp}}{4L}
\]

\[
\leq \frac{L}{\sigma} (\varepsilon_{mp} + \varepsilon_{mp}) = \left(\frac{L}{\sigma} + \frac{\beta}{4L}\right) \varepsilon_{mp}
\]

where (a) uses triangle inequality, and (b) uses (35) and (37), and (c) uses (39) and the fact that \( R = \log_2 \frac{2LL}{\varepsilon_{mp}} \). Finally, we prove that \((x_R, y_{R+1})\) satisfies (21).

\[
g(\hat{x}_R, y_{R+1}) \leq g(x^*(y_{R+1}), y_{R+1}) + \langle \nabla y g(x^*(y_{R+1}), y_{R+1}), \hat{x}_R - x^*(y_{R+1}) \rangle + \frac{L}{2} \|x^*(y_{R+1}) - \hat{x}_R\|^2
\]

\[
\leq \min_x g(x, y_{R+1}) + 0 + \frac{25LL^2\varepsilon_{mp}^2}{8\sigma^2} \|x - y_{R+1}\|^2
\]

where (a) uses \( L \)-smoothness of \( g(\cdot, y) \), (b) uses necessary first order optimality condition: \( \langle \nabla y g(x^*(y), y), x - x^*(y) \rangle = 0 \) and (c) uses \( \varepsilon_{mp} = \frac{2\sigma}{\sqrt{L}} \sqrt{\frac{2\varepsilon_{mp}}{L}} \).

Let the number of gradient computations done per iteration of Imp-STEP (a run of accelerated gradient ascent) be \( T_r \) and \( \kappa = \sqrt{L/\sigma} \). Then, from guarantee on AGD (32) (Eqn. (5.68)), we get that,

\[
g(\hat{x}_r, y_r) - g(x^*(y), y_r) \leq \left(1 + \frac{1}{\sqrt{\kappa} - 1}\right) - T_r \left( g(x_0, y_r) - g(x^*(y_r), y_r) + \frac{\sigma}{2} \|x_0 - x^*(y_r)\|^2 \right)
\]

\[
\leq e^{-T_r/\sqrt{\kappa}} 2g(x_0, y_r) - g(x^*(y_r), y_r)\rangle
\]

\[
\leq e^{-T_r/\sqrt{\kappa}} 2(f(x_0) - h(y_r))
\]

\[
\leq e^{-T_r/\sqrt{\kappa}} 2(f(x_0) - \min_{y' \in D_Y} h(y'))
\]

where \( \min_{y' \in D_Y} h(y') \) is well-defined since \( D_Y \) is compact and \( h \) is smooth (Lemma 6). This means that if we want \( g(\hat{x}_r, y_r) - g(x^*(y_r), y_r) \leq \varepsilon_{agd} \), then required number of steps \( T_r \) is at most,

\[
\left[ \frac{T_r}{\sigma} \log \frac{50L(f(x_0) - \min_{y' \in D_Y} h(y'))}{\varepsilon_{agd}} \right] = \left[ \frac{T_r}{\sigma} \log \frac{50L(f(x_0) - \min_{y' \in D_Y} h(y'))}{\varepsilon_{step}} \right] = O\left( \frac{T_r}{\sigma} \log \left( \frac{1}{\varepsilon_{step}} \right) \right)
\]

### B.6 Smoothness of dual of strongly-convex–concave minimax problem

**Lemma 6.** For a \( \sigma \)-strongly-convex–concave \( L \)-smooth function \( g(\cdot, \cdot) \), \( h(u) = \min_{x \in X} g(x, u) \) is an \( (L + \frac{L^2}{\sigma}) \)-smooth concave function.

**Proof.** We know that \( h(y) = \min_{x \in X} g(x, y) \), where \( g(\cdot, y) \) is \( \sigma \)-strongly convex, \( g(x, \cdot) \) is concave, \( h \) is \( L \)-smooth (Definition 1). Since \( g(\cdot, y) \) is strongly convex, the minimizer \( x^*(y) = \arg \min_{x \in X} g(x, y) \) unique. Then by Danskin’s theorem [4] Section 6.11], \( h \) is differentiable and \( \nabla h(y) = \nabla_y g(x^*(y), y) \). Then \( h \) can be show to be smooth as follows,

\[
\|\nabla h(y_1) - \nabla h(y_2)\| \leq \|\nabla_y g(x^*(y_1), y_1) - \nabla_y g(x^*(y_2), y_2)\|
\]

\[
\leq \|\nabla_y g(x^*(y_1), y_1) - \nabla_y g(x^*(y_1), y_2)\| + \|\nabla_y g(x^*(y_1), y_2) - \nabla_y g(x^*(y_2), y_2)\|
\]

\[
\leq L\|y_1 - y_2\| + L\|x^*(y_1) - x^*(y_2)\|
\]

\[
\leq L\|y_1 - y_2\| + L\frac{L}{\sigma}\|y_1 - y_2\| = \left( L + \frac{L^2}{\sigma}\right)\|y_1 - y_2\|
\]

where (a) uses \( L \)-smoothness of \( g \) and (b) uses (35). 

\( \square \)
We now divide the analysis of each iteration of our algorithm into two cases:

**Case 1:** \( \hat{f}(x_{k+1}; x_k) \leq f(x_k) - 3\varepsilon/4 \). As every instance of Case 1 ensures \( f(x_{k+1}) \leq \hat{f}(x_{k+1}; x_k) \leq f(x_k) - 3\varepsilon/4 \), we can have only \( \left\lceil \frac{4(f(x_0) - f^*)}{3\varepsilon} \right\rceil \) Case 1 steps before termination. This claim requires monotonic decrease in \( \hat{f}(x_k) \) which holds until \( f(x_{k+1}) \geq f(x_k) \), after which \( \hat{f}(x_{k+1}; x_k) \geq f(x_k) \), which in-turn imply that Prox-DIAG terminates (see termination condition of Prox-DIAG).

**Case 2:** \( \hat{f}(x_{k+1}; x_k) > f(x_k) - 3\varepsilon/4 \): In this case, we show that \( x_k \) is already an \( \varepsilon \)-FOSP and the algorithm returns \( x_k \).

\[
\hat{f}(x_k; x_k) + \frac{L}{2} \|x_k - x_k\|^2 \leq \hat{f}(x_k; x_k) = f(x_k) \leq f(x_k) < \hat{f}(x_k; x_k) + \varepsilon \quad \text{implies} \quad \|x_k - x_k\| < \sqrt{\frac{2\varepsilon}{L}}
\]

where (a) uses (45). Now consider any \( \bar{x} \in X \), such that \( 4\sqrt{\varepsilon/L} \leq \|\bar{x} - x_k\| \). Then,

\[
f(\bar{x}) + L\|\bar{x} - x_k\|^2 = \max_{y \in Y} g(\bar{x}, y) + L\|\bar{x} - x_k\|^2 = \hat{f}(\bar{x}; x_k) \geq \hat{f}(x_k; x_k) + \frac{L}{2} \|\bar{x} - x_k\|^2
\]

where (a) uses \( \varepsilon \)-strong convexity of \( \hat{f}(\cdot; x_k) \) at its minimizer \( x_k \). (b) uses (45), and (b) and (c) use triangle inequality. (46) and \( 4\sqrt{\varepsilon/L} \leq \|\bar{x} - x_k\| \).

Now consider the Moreau envelope, \( \hat{f} \). \( \hat{f}(x, x') = \min_{x' \in X} \phi_{x} (x') \) where \( \phi_{x} (x') = f(x') + L\|x - x'\|^2 \). Then, we can see that \( \phi_{x} (x') \) achieves its minimum in the ball \( \{x' \in X : \|x' - x_k\| \leq 4\sqrt{\varepsilon/L} \} \) by (47) and Lemma 4. Then, with Lemma 4(b,c), we get that,

\[
\|\nabla \hat{f}(\hat{x}; x_k)\| \leq (2L)\|x_k - \hat{x}; x_k\| = 8\sqrt{L}\varepsilon = \varepsilon
\]

i.e., \( x_k \) is an \( \varepsilon \)-FOSP.

By combining the above two cases, we establish that \( O \left( \frac{L(f(x_0) - f^*)}{\varepsilon} \right) \) “outer” iterations ensure convergence to a \( \varepsilon \)-FOSP. We now compute the first-order complexity of each of these “outer” iterations. Recall that we use use the DIAG (Algorithm 1) algorithm for \( L \)-strongly-convex concave 2L-smooth minimax problem to solve the inner optimization problem. So, if for each iteration of inner problem, DIAG algorithm takes \( K \) steps then, by \( \hat{\varepsilon} = \frac{\varepsilon^2}{28L} \) and Theorem 1

\[
\frac{6(2L)^2D^2}{LK^2} \leq \frac{\varepsilon^2}{4} = \frac{\varepsilon^2}{28L} \quad \Rightarrow \quad O \left( \frac{LD\sqrt{\nu}}{\varepsilon} \right) \leq K
\]

Therefore the number of gradient computations required for each iteration of inner problem is \( O \left( \frac{LD\sqrt{\nu}}{\varepsilon} \right) \) (Theorem 1), which along with the bound on the number of outer iterations establishes the Theorem’s upper bound on the number of first-order oracle calls.

C Minimizing finite max-type function with smooth components

As a special case of nonconvex–concave minimax problem, consider minimizing a weakly convex \( f(x) \), with a special structure of finite max-type function:

\[
\min_{x} \left[ f(x) = \max_{1 \leq i \leq m} f_i(x) \right],
\]

(P3)
where \( x \in \mathbb{R}^p \), the functional components \( f_i(x) \)'s could be nonconvex but are \( L \)-smooth and \( G \)-Lipschitz. Suppose \( f \) itself takes a minimum value \( f^* > -\infty \). For this problem, we propose and study a proximal (Prox-FDIAG) algorithm (Algorithm 5) presented in Appendix C.1 that is inspired by Algorithm 2 with the inner problem-solver replaced by Nesterov’s finite convex minimax scheme \( \text{Algorithm 2} \) instead of Algorithm 1. Using same proof technique as Theorem 2 we get:

**Corollary 1** (Convergence rate of Prox-FDIAG). If the functional components \( f_i(x) \)'s are \( G \)-Lipschitz and \( L \)-smooth, and the optimal solution is bounded below, i.e. \( f(x) \geq f^* > -\infty \), then after: \( K = \left\lceil \frac{4L(f(x_0) - f^* - 1)}{3\varepsilon^2} \right\rceil \) outer steps, Prox-FDIAG outputs an \( \varepsilon \)-FOSP. The total first-order oracle complexity to find \( \varepsilon \)-FOSP is: 

\[
\frac{4L(f(x_0) - f^*)}{3\varepsilon^2} \cdot \frac{2^4G(m \log^{3/2} m)}{\varepsilon}.
\]

See Appendix C.1 for a proof. Current best rate for this problem is achieved by subgradient methods. As the subgradient of a finite minimax function \( \nabla_i f(x) \) is easy to evaluate, where \( i^* \in \arg\max f_i(x) \), a rate of \( O(m/\varepsilon^4) \) first-order oracle and function calls is achieved by the state-of-the-art subgradient method in [11]. We can obtain a similar result using Algorithm 1 but it requires extension to non-Euclidean settings with the framework of Bregman divergences. This is fairly standard and will be updated in the next version of the paper.

**Algorithm 5:** Proximal Finite Dual Implicit Accelerated Gradient (Prox-FDIAG) for finite nonconvex concave minimax optimization

**Input:** functional components \( \{f_i\}_{i=1}^m \), Lipschitzness \( G \), smoothness \( L \), domain \( \mathcal{X} \), target accuracy \( \varepsilon \), initial point \( x_0 \)

**Output:** \( x_k \)

1. \( \bar{\varepsilon} \leftarrow \frac{\varepsilon}{mL} \)
2. for \( k = 0, 1, \ldots \) do
   3. Using excessive gap technique [35] Problem (7.11)] for strongly convex components, find \( x_{k+1} \in \mathcal{X} \) such that,
      \[
      \hat{f}(x_{k+1}; x_k) \leq \min_x \hat{f}(x; x_k) + \bar{\varepsilon}/4
      \]  
      (50)
   4. if \( f(x_k) - 3\bar{\varepsilon}/4 < \hat{f}(x_{k+1}; x_k) \) then
      return \( x_k \)

**C.1 Proof of Corollary 1**

Let

\[
\hat{f}(x; x_k) = \max_{1 \leq i \leq m} f_i(x_k) + \langle \nabla f_i(x_k), x - x_k \rangle + \frac{L}{2} \| x - x_k \|^2
\]

be a quadratic approximation of the finite max-type function \( f(x) \) at \( x_k \). Then, \( \hat{f}(x; x_k) \) is \( L \)-strongly convex, since it is a maximum of convex functions and the quadratic term in (51) is independent of \( i \).

Proof is similar to that of Theorem 2. We divide the analysis of each iteration of our algorithm into two cases.

**Case 1:** \( \hat{f}(x_{k+1}; x_k) \leq f(x_k) - 3\bar{\varepsilon}/4 \). This ensures that at iteration \( k \) the objective value decreases by at least \( 3\bar{\varepsilon}/4 \) since, \( f(x_{k+1}) \leq \hat{f}(x_{k+1}; x_k) \leq f(x_k) - 3\bar{\varepsilon}/4 \). One cannot have more than \( \left\lceil \frac{4(f(x_0) - f^*)}{3\bar{\varepsilon}} \right\rceil \) instances of Case 1, before termination.

**Case 2:** \( \hat{f}(x_{k+1}; x_k) > f(x_k) - 3\bar{\varepsilon}/4 \): We show that \( x_k \) is an \( \varepsilon \)-FOSP as follows:

\[
 f(x_k) - \frac{3\bar{\varepsilon}}{4} < \hat{f}(x_{k+1}; x_k) \leq \min_x \hat{f}(x; x_k) + \frac{\bar{\varepsilon}}{4} \implies f(x_k) < \min_x \hat{f}(x; x_k) + \bar{\varepsilon}
\]

(52)
Define $x_k^*$ as the point satisfying $x_k^* = \arg\min_x \hat{f}(x; x_k)$. By $L$-strong convexity of $\hat{f}(\cdot, x_k)$ \eqref{eq:strong_convexity}, we prove that $x_k$ is close to $x_k^*$:

$$
\hat{f}(x_k^*; x_k) + \frac{L}{2} \|x_k - x_k^*\|^2 \leq \hat{f}(x_k^*; x_k) = f(x_k) \leq \hat{f}(x_k; x_k) + \bar{\varepsilon}
$$

$$
\implies \|x_k - x_k^*\| < \sqrt{\frac{2\bar{\varepsilon}}{L}}
$$

\eqref{eq:inequality} where \(a\) uses \eqref{eq:strong_convexity}. Now consider any $\hat{x} \in \mathcal{X}$, such that $4\sqrt{\bar{\varepsilon}/L} \leq \|\hat{x} - x_k\|$. Then, 

$$f(\hat{x}) + L\|\hat{x} - x_k\|^2 = \max_i f_i(\hat{x}) + L\|\hat{x} - x_k\|^2 \geq \max_i f_i(x_k) + \frac{L}{2}\|\hat{x} - x_k\|^2$$

$$\geq \hat{f}(\hat{x}; x_k) + \frac{L}{2}\|\hat{x} - x_k^*\|^2$$

$$\geq f(x_k) - \bar{\varepsilon} + \frac{L}{2}(\|\hat{x} - x_k\| - \|x_k - x_k^*\|)^2$$

$$\geq f(x_k) - \bar{\varepsilon} + 2\bar{\varepsilon} = f(x_k) + \bar{\varepsilon}$$

\eqref{eq:inequality} where \(a\) uses weak convexity of $f_i$, \(b\) uses \eqref{eq:strong_convexity}, \(c\) uses $L$-strong convexity of $\hat{f}(\cdot; x_k)$ at its minimizer $x_k^*$, \(d\) uses \eqref{eq:strong_convexity}, and \(b\) and \(e\) use triangle inequality, \eqref{eq:inequality} and $4\sqrt{\bar{\varepsilon}/L} \leq \|\hat{x} - x_k\|$.

Now consider the Moreau envelope, $f_{\lambda, x}(x) = \min_{x' \in \mathcal{X}} \phi_{\frac{1}{\lambda}, x}(x')$ where $\phi_{\lambda, x}(x') = f(x') + \lambda\|x - x'\|^2$. Then, we can see that $\phi_{\lambda, x}(x')$ achieves its minimum in the ball $\{x' \in \mathcal{X} | \|x' - x_k\| \leq 4\sqrt{\bar{\varepsilon}/L}\}$ by \eqref{eq:inequality} and Lemma \ref{lem:triangle}. Thus, with Lemma \ref{lem:triangle}, we get that

$$\|\nabla f_{\lambda, x}(x_k)\| \leq (2L)\|x_k - \hat{x}_{1/2L}(x_k)\| = 8L \bar{\varepsilon} = \varepsilon$$

Now we use the excessive gap technique for non-smooth strongly convex functions with max-structure to solve the inner optimization problem in $4G(m \log m)\sqrt{\frac{\log m}{\varepsilon L}}$ computations \[35\] Problem (7.11).

Putting these together we see that the total number of inner steps to reach $\varepsilon$-FOSP is

$$\left\lceil \frac{4(f(x_0) - f^*)}{3\bar{\varepsilon}} \right\rceil \left\lceil 2G(m \log m)\sqrt{\frac{\log m}{\varepsilon L}} \right\rceil = \left\lceil \frac{4L(f(x_0) - f^*)}{3\varepsilon^2} \right\rceil \left\lceil \frac{2G}{\varepsilon}(m \log^{3/2} m) \right\rceil$$

\eqref{eq:inner_steps}

C.2 Adaptive Prox-FDIAG algorithm

In this section, we provide the Adaptive Prox-FDIAG (Algorithm \ref{alg:adaptive_prox_fdiag}) to find an $\varepsilon$-FOSP of the finite max-type nonconvex minimax problem \[33\] with $L$-smooth components. Adaptive Prox-FDIAG is a variation of the Prox-FDIAG (Algorithm \ref{alg:prox_fdiag}). Adaptive Prox-FDIAG uses Prox-FDIAG as a sub-routine and successively finds $\varepsilon'$-FOSPs, for geometrically decreasing values of $\varepsilon'$ starting from $\varepsilon_0 (\geq \varepsilon)$ until $\varepsilon'$ becomes equal to $\varepsilon$. It uses the $\varepsilon'$-FOSP as the starting point to find an $\varepsilon'/2$-FOSP. In the following corollary, we show that Adaptive Prox-FDIAG has the same the first-order oracle complexity (up to a $O(\log(\frac{1}{\varepsilon}))$ factor) as the Prox-FDIAG.

\textbf{Corollary 2 (Convergence rate of Adaptive Prox-FDIAG).} If the functional components $f_i(x)$’s are $G$-Lipschitz and $L$-smooth, and the optimal solution is bounded below, i.e. $f(x) \geq f^* > -\infty$, then after: $K = \left\lceil \log_2 \frac{\varepsilon_0}{\varepsilon} \right\rceil$ outer steps, Adaptive Prox-FDIAG outputs an $\varepsilon$-FOSP. The total first-order oracle complexity to find $\varepsilon$-FOSP is:

$$\log_2 \frac{\varepsilon_0}{\varepsilon} \left\lceil \frac{4L(f(x_0) - f^*)}{3\varepsilon^2} \right\rceil \cdot \left\lceil \frac{2G}{\varepsilon}(m \log^{3/2} m) \right\rceil$$

\eqref{eq:outer_steps}

\textbf{Proof.} Notice that, each iteration of Adaptive Prox-FDIAG for finding an $\varepsilon'$-FOSP, is a run of Prox-FDIAG (Algorithm \ref{alg:prox_fdiag}), which has a maximum first-order oracle complexity of $\left\lceil \frac{4L(f(x_0) - f^*)}{3\varepsilon^2} \right\rceil$.

22
[\frac{2G}{\varepsilon} (m \log^{3/2} m)] for finding an \( \varepsilon’ \)-FOSP (Corollary 1), as \( \varepsilon \leq \varepsilon’ \). Further, since \( \varepsilon’ \) starts at \( \varepsilon_0 \) and halves after each iteration until \( \varepsilon’ \) becomes less than or equal to \( \varepsilon \), the total number of outer iterations is 
\[ K = \left\lceil \log_2 \frac{\varepsilon_0}{\varepsilon} \right\rceil. \]

Therefore, Adaptive Prox-FDIAG has the same first-order oracle complexity as Prox-FDIAG, up to a \( O(\log(\frac{1}{\varepsilon})) \) factor. However, we observe that Adaptive Prox-FDIAG converges faster than Prox-FDIAG in our experiments.

**Algorithm 6:** Adaptive Proximal Finite Dual Implicit Accelerated Gradient (Adaptive Prox-FDIAG) for finite nonconvex concave minimax optimization

**Input:** functional components \( \{f_i\}_{i=1}^m \), Lipschitzness \( G \), smoothness \( L \), domain \( \mathcal{X} \), target accuracy \( \varepsilon \), initial point \( x_0 \), initial accuracy \( \varepsilon_0 \)

**Output:**

1. \( \varepsilon’ \leftarrow \max(\varepsilon_0, \varepsilon) \)
2. for \( k = 0, 1, \ldots \) do
   3. Using Prox-FDIAG (Algorithm 5) initialized at \( x_k \), find \( x_{k+1} \in \mathcal{X} \) such that \( x_{k+1} \) is an \( \varepsilon’ \)-FOSP (Definition 6) of the function \( f(x) = \max_{1 \leq i \leq m} f_i(x) \)
   4. if \( \varepsilon = \varepsilon’ \) then
      5. \( k \leftarrow k + 1 \)
      6. return \( x_k \)
   7. else
      8. \( \varepsilon’ \leftarrow \max(\varepsilon’, \varepsilon) \)

**D Smoothing technique for strongly-convex–concave minimax problem**

In this section we propose and analyze a smoothing technique [36] based indirect algorithm for solving the \( L \)-smooth \( \sigma \)-strongly-convex–concave minimax problem. The basic idea is to solve a smoothed (perturbed) version of the original function, \( \tilde{g}(x, y) = g(x, y) - \varepsilon y^2 / 2 D_y^2 \), which would be a strongly-convex–strongly-concave minimax problem. [1] proposes solving a strongly-convex–strongly-concave problem in linear rate using inexact accelerated gradient descent on its dual, whose main guarantee is given in the theorem below.

**Theorem 3.** [1] Inexact accelerated gradient ascent on the dual problem can find an \( \varepsilon’ \)-primal dual pair of an \( L \)-smooth \( \sigma_x \)-strongly-convex–\( \sigma_y \)-strongly-concave problem: \( \min_{x} \max_{y} g(x, y) \), with
\[
\tilde{O}\left( \sqrt{\frac{L}{\sigma_x}} \sqrt{\frac{\sigma_y}{\sigma}} \right) \quad \text{calls to the first order gradient oracle of } g.
\]

Now using this algorithm on the function \( \tilde{g} \) can recover the same rate as DIAG method as follows. Plugging in \( L = \tilde{O}(L), \sigma_x = \sigma, \) and \( \sigma_y = \varepsilon / D_y^2 \) into the algorithm complexity of Theorem 3 gives you a complexity of,
\[
\tilde{O}\left( \frac{LD_y}{\sqrt{\sigma} \sqrt{\frac{\sigma}{\varepsilon}}} \right),
\]
finding an \( \varepsilon \)-primal dual pair, \((\bar{x}, \bar{y})\), of \( \tilde{g} \). Since
\[
\max_{y \in Y} g(\bar{x}, y) \leq \max_{y \in Y} \tilde{g}(\bar{x}, y) + \varepsilon / 2 \quad \text{and} \quad \tilde{g}(\bar{x}, y) \leq g(\bar{x}, y) + \tilde{g}(x, \bar{y}) + O(\varepsilon).
\]

Using these two facts, we see that smoothing technique has the same algorithmic complexity, \( \tilde{O}\left( \frac{LD_y}{\sqrt{\sigma} \sqrt{\frac{\sigma}{\varepsilon}}} \right) \), as that of DIAG. However the drawback for this method over the direct DIAG is that smoothing technique requires a prefixed tolerance parameter \( \varepsilon \).
We consider the following problem.

\[ \min_{x \in \mathbb{R}^2} \left[ f(x) = \max_{1 \leq i \leq m=9} f_i(x) \right] \]  

(57)

where \( f_i(x) = q_{(-1,X_i^{(1)}),c_i}(x) \) for all \( 1 \leq i \leq 8 \), where \( q_{(a,b,c)}(x) = a\|x - b\|^2_2 + c \), \( X_i^{(1)} \) and \( X_i^{(2)} \) are generated from the interval \([-3.0, 3.0]\) uniformly at random, and \( c_i \) is generated from the interval \([1.0, 5.0]\) uniformly at random. We fix the last component \( f_9(x) = q_{(0.5,(0.0),0)}(x) \). Each \( f_i \) is smooth with parameter \( L = 1 \), which implies that \( f \) is \( L \)-weakly convex.

We implement three algorithms: Prox-FDIAG (Algorithm 5), Adaptive Prox-FDIAG (Algorithm 6), and subgradient method [11]. In Prox-FDIAG, we use excessive gap technique [35] Problem (7.10) (a primal-dual algorithm) to solve the inner sub-problem. As the stopping criteria \( \hat{f}(x_{k+1};x_k) \leq \min_{x} \hat{f}(x; x_k) + \varepsilon/4 \) cannot be directly checked, we instead check a sufficient condition; we stop the excessive gap technique when the primal-dual gap is less than \( \varepsilon/4 \), which can be checked efficiently. Adaptive Prox-FDIAG is a variant of Prox-FDIAG, where we adaptively and successively decrease the tolerance parameter \( \epsilon' \) starting from a large tolerance \( \epsilon_0 \). It has the same first-order oracle complexity guarantee as Prox-FDIAG (up to an \( O(\log(1/\varepsilon)) \) factor). However, in Figure 1 we observe that Adaptive Prox-FDIAG can converge faster in practice. We set the initial tolerance \( \epsilon_0 \) as 10.0. For a description of the algorithm we refer to Appendix E.

All the algorithms are initialized with the point \( x_0 = (4, 4) \) and are given a Lipschitz constant parameter of \( G = 2L\|\mathbf{x}\|_2 \). We run the algorithms ten times with randomly generated instances of the objective function \( f(x) \). In Figure 1, we plot the norm of gradient of Moreau envelope \( \|\nabla f_{\mathbf{x}}(x_k)\|_2 \) against the number of iterations \( k \) in log-log scale. We compute the gradient of the Moreau envelope at any point \( x \), by solving the corresponding convex-concave saddle point problem (18) using Mirror-Prox [34] method with appropriate primal-dual gap based stopping criteria and then using Lemma 4(c). For Prox-FDIAG (red circles), we show in a scatter plot the gradient norm \( \|\nabla f_{\mathbf{x}}(x_{k(c)})\|_2 \) at the final output of Prox-FDIAG \( x_{k(c)} \) versus the total number of inner iterations (of excessive gap technique) taken, for \( \varepsilon = 10^0, 10^{-1}, 10^{-2}, 10^{-3} \) over the 10 functions. For Adaptive Prox-FDIAG (black dots) in a scatter plot, we plot the gradient norm \( \|\nabla f_{\mathbf{x}}(x')\|_2 \) at the output \( x' \) of each inner sub-problem (excessive gap technique) of each inner Prox-FDIAG step versus the total number of inner iterations (of excessive gap technique) taken to reach that point from the beginning, for \( \varepsilon = 10^{-7} \) over the 10 functions. For Prox-FDIAG and Adaptive Prox-FDIAG, using solid red and black (respectively) lines we also plot the best linear function (in log-scale) which fits the scatter points (using default parameters of scipy.stats.linregress[2]). For the subgradient method (blue triangles), we plot the mean and standard error of gradient norm \( \max_{0 \leq k' \leq k} \|\nabla f_{\mathbf{x}}(x_{k(k)})\|_2 \) over the 10 instances at iterations \( k = 10^0, 10^1, \ldots, 10^7 \). The estimate at each iteration is the best one so far in the function value, i.e. \( \hat{k}(k) \in \arg\min_{0 \leq k' \leq k} f(x_{k'}) \). We see that, Prox-FDIAG and Adaptive Prox-FDIAG have a faster convergence rate than subgradient method. Further, in the same vein as analogous variants in convex non-smooth optimization, Adaptive Prox-FDIAG is faster than Prox-FDIAG almost always.

Subgradient method has a theoretical convergence rate of \( O(\frac{1}{\sqrt{K}}) \) for a fixed number of iterations \( K \) and a constant step-size \( \gamma/\sqrt{K+1} \) [11] Corollary 2.2. However, similar to the case of convex non-smooth problems, we observe that fixed step-size results in a slow convergence. In our experiments, we achieve a faster convergence for the subgradient method by using a diminishing, non-summable but square-summable step-size, \( \gamma/\sqrt{k+1} \), which varies with the iteration number \( k \). This step-size has convergence rate of \( O\left(\frac{\log(k)}{k}\right) \) [11] Theorem 2.1, but in practice we observe a faster convergence rate than the constant step-size. After a very simple parameter search, we set \( \gamma \) as 0.1 \( \times G \times L^{3/2} \). We ran subgradient method for a total of \( K = 10^7 \) number of iterations. Since, subgradient method is not a descent method, at any iteration \( k \), we keep track of the best point among all the points we have observed so far, \( \{x_0, \ldots, x_{k-1}\} \). Ideally, we should keep track of the point with the minimum norm for the gradient of the Moreau envelope, \( \|\nabla f_{\mathbf{x}}(x_k)\|_2 \), but since the computation of the gradient of Moreau envelope is costly, we only keep track of the point with the minimum function value we have observed so far.
